

ABSTRACT

The invention relates to a PCS-server of a personal communication system providing personal telephone numbers for PCS subscribers. A PCS subscriber can send a handling message to the PCS-server and can form a specific handling of one or more destination profiles stored in a destination profile memory. The specific handling relates to the specific selection and activation/deactivation or switching between specific destination profiles or to the setting of specific call distribution criteria in the destination profiles. The call distribution criteria relate to origin parameter teleservice-type parameters, busy option parameters and number of call parameters. The PCS subscriber can therefore flexibly configure and use the destination profiles allocated to his personal telephone number. Based on the selected call distribution criteria a flexible delivery of the calls by using the so-set destination profiles is possible.
